BACKGROUND OF THE INVENTION

1. Field of the Invention

The invention relates to a method for changing the section of a billet of a continuous casting plant during continuous casting operation wherein opposed sides of the billet are in operative contact with oppositely arranged roll supports positioned below a casting die, wherein the roll supports are divided into sequentially arranged segments that support rolls and are connected to one another by jointed connections, wherein each segment is independently adjustable with regard to an angle relative to the billet, and wherein in an initial position the billet guide to be changed is adjusted to a uniform production format thickness (section of the billet). The invention also relates to a device for performing the method.

2. Description of the Related Art

The change of section of a billet in continuous casting plants during the continuous casting operation is an absolute requirement for optimizing production. However, in the past it was necessary to reduce the casting speed for a period of time for the purpose of thickness (section)

reduction or thickness (section) increase. This results in production losses, and the entire course of the production is at least momentarily thrown off balance. Moreover, in the currently practiced methods it is only possible to perform a fixedly adjusted, stepped change of section.

The patent document EP 0 450 391 B1 discloses a device for supporting a metal billet, especially for soft reduction, in a strip casting plant wherein below the continuous casting die on both sides of the billet mirror-symmetrically and oppositely arranged roll supports are provided whose rolls are in operative contact with the billet. Each roll support is arranged on a stationary frame and divided into several roll-supporting segments which are connected to adjusting devices. The roll-supporting segments are connected with articulation to one another such that each segment can be independently adjusted at any desired angle relative to the billet and fixed in this position, wherein the upper adjusting device is used for the general adjustment of the roll support. This adjusting device can be a mechanical, a hydraulic or a mechanic-hydraulic adjusting device.

The patent document DE 43 38 805 C2 discloses a method and a device for operating a continuous casting plant,

especially for cast-on of a continuous casting plant for producing thin slabs for hot strip rolling, with at least one reduction roll pair arranged downstream of the continuous casting die. Moveable thin slab guiding elements are positioned downstream of the reduction roll pair. The reduction roll pair is adjusted, after a predetermined length of the hot strip has passed through, to a smaller gap width which results in squeezing off of the liquid phase. The hot strip is shaped to a cast-on format having a thickness which is less than the thickness of the desired final format. The strip guiding elements, respectively, the reduction roll pair, are subsequently, preferably successively, adjusted to the thickness of the final format as soon as the cast-on format of reduced thickness is completely positioned within their adjusting area. The reduction roll pair is pressure-controlled and is positioned in accordance with the final format after the strip guiding elements have been advanced.

The patent document EP 0 743 116 A1 discloses a vertical casting production line for billets, comprising a casting die as well as a component group with foot rolls downstream of the exit of the casting die, moreover a plurality of guiding units, a correlated vertical roll segment as well as a driver arrangement in connection with a

SUMMARY OF THE INVENTION

It is an object of the present invention to provide a method as well as a device suitable for performing the method for format thickness change (change of section) of the billet of a continuous casting plant during continuous casting, in which the casting speed for the transitional process to the change of section is not reduced, i.e., constant production and casting conditions are maintained. The transitional length of the billet during the change a section is to be shortened for the purpose of avoiding production losses. In all transitional situations of the change of section an optimal billet support is to be ensured for reducing break-out risks.

In accordance with the present invention, this is achieved in that the change of section is carried out in a controlled sequence of adjusting steps of the segments, in particular, in that

- a sequential advancement of the sequentially arranged segments at their jointed connections in the casting direction is performed for reducing the format thickness or section, and
- a sequential moving away of the sequentially arranged segments at their jointed connections in the casting

direction is performed for increasing the format thickness or section.

With the disclosed course of the method for a change of section for continuous casting plants the following is achieved:

In a further embodiment of the method it is suggested that for a format thickness reduction with constant casting speed, wherein the solidification point of the billet 9 is, for example, in the segment $n = 3$, the exit side of the first segment $n = 1$ is advanced via the jointed connection with the inlet side of the segment $n = 2$ by set-point control in a first adjusting phase, and, after reaching the target position, i.e., the segment position for the target format, the exit side of the segment $n = 2$ is advanced together with the inlet side of the segment $n = 3$ in a second adjusting phase, and in a sequence of identical steps the adjustments of the segments $n = 3, 4$ to i to the target position is carried out.

According to another embodiment of the invention, it is proposed that for a format thickness increase at constant casting speed, wherein the liquid phase tip of the billet is, for example, located in the segment $n = 3$, first the exit side of the segment $n = 1$ is moved away at the jointed connection together with the inlet side of the segment $n = 2$ by set-point control in a first adjusting phase, and, after reaching the target position, i.e., the segment position for the target format, the exit side of the segment $n = 2$ together with the inlet side of the segment $n = 3$ is moved away in a second adjusting phase, and in a sequence of

identical steps the adjustment of the segments $n = 3, 4$ to i to the target position is carried out.

According to a further embodiment of the method of the invention, it is proposed that the advancing of the segments is carried out with constant speed by dynamic position control, wherein a predetermined force threshold value is not surpassed.

Moreover, it is suggested according to the invention to calculate the adjusting speed of the segments by taking into consideration the permissible billet elongation limit and the current casting speed in connection with the current format adjustment, respectively, according to the resulting volume flow of the billet. Advantageously, the adjusting speed is calculated via the current casting speed, the segment length, and the required adjusting stroke according to the equation

$$V = Ds/Ls * V_{\text{cast}}$$

wherein Ds is the format thickness change (change of section), Ls is the segment length, and V_{cast} is the current casting speed.

Further developments of the method propose that the adjusting process is monitored, for example, by the current

BRIEF DESCRIPTION OF THE DRAWING

In the drawing:

Fig. 1 shows the sequence of adjusting steps of the method according to the invention, illustrated in sequential phases, for format thickness reduction; and

Fig. 2 shows the sequence of adjusting steps of the method according to the invention, illustrated in sequential phases, for format thickness increase.

segment 1 and the inlet side of the segment 2 are advanced with constant speed by dynamic position control by means of set-point control. A predetermined force threshold value is not surpassed. The advancing speed is calculated taking into consideration the permissible billet elongation limit and the current casting speed in connection with the current format adjustment, respectively, according to the thus resulting volume flow of the billet.

The adjusting speed to be maintained is calculated based on the current casting speed, the segment length, and the required adjusting stroke according to the equation

$$V = Ds/Ls * Vcast$$

wherein Ds is the format thickness change, Ls is the segment length, and $Vcast$ is the current casting speed.

An effective force monitoring action, computable, for example, via the current cylinder pressures of a hydraulic adjusting device, monitors the adjusting process. Should the force surpass a calculated threshold value or limit, the method switches from position control to force control. After reaching the target position, the method switches back to position control.

With the described course of the method, it is achieved

out in analogy to that of the exit side of segment 2.

As soon as the target format of the inlet side of the segment 3 has been reached, the exit side of the segment 3 and the inlet side of the segment 4 (phase 3) are moved away from the billet (gap is widened). The calculation of the casting speed and the monitoring action are carried out as disclosed above.

As soon as the target format of the inlet side of segment 4 has been reached, the exit side of segment 4 (phase 4) is moved away from the billet. The calculation for the monitoring action is carried out as disclosed above.

While specific embodiments of the invention have been shown and described in detail to illustrate the inventive principles, it will be understood that the invention may be embodied otherwise without departing from such principles.
